In the SAMURAI30 experiment, we studied the Gamow-Teller (GT) giant resonance in the drip-line nucleus  ${}^{11}\text{Li}$  at 181 MeV/nucleon utilizing the missing-mass technique.<sup>1)</sup> The  ${}^{11}\text{Li}$  nucleus is the showcase of a two-neutron halo system, with its very extended matter distribution related to the small energy necessary to remove the neutrons. The charge-exchange ( $p, n$ ) reactions in inverse kinematics are efficient tools to extract the B(GT) strengths of unstable isotopes up to high excitation energies without the  $Q$ -value limitation.<sup>2)</sup> In our previous study, we demonstrated that accurate information about isovector spin-flip giant resonances can be obtained for unstable nuclei using this probe.<sup>3)</sup> The setup of the PANDORA low-energy neutron time-of-flight counter<sup>4)</sup> and SAMURAI magnetic spectrometer<sup>5)</sup> as well as a thick liquid hydrogen target, facilitate the performance of measurements with high luminosity.

The  $\beta$  decay of  ${}^{11}\text{Li}$  is complex. The large mass difference between  ${}^{11}\text{Li}$  and its daughter  ${}^{11}\text{Be}$  ( $Q = 20.6$  MeV) implies that several decay channels to the bound and unbound states in  ${}^{11}\text{Be}$  are open. In the latter cases, the daughter breaks into fragments, and the emission of one, two, and three neutrons,  $\alpha$  particles and  ${}^6\text{He}$ , tritons, and deuterons has been observed in several  $\beta$ -decay studies.<sup>6,7)</sup> In our previous reports<sup>8)</sup> on the preliminary results on GT giant resonance, the

observation of these different decay channels was confirmed. Among them, the most interesting decay mode is  ${}^9\text{Li} + d$ . This channel is related to the possibility that in halo nuclei, the core and halo particles could decay, more or less independently, into different channels.<sup>9)</sup>

We observed a strong transition at approximately 19 MeV in the excitation energy spectrum of  ${}^{11}\text{Be}$ . The angular distribution in center-of-mass angle of the observed state indicates a strong forward peaking nature, which suggests the GT transition, as depicted in Fig. 1, in agreement with previous  $\beta$ -decay studies.

Fig. 1. Angular distribution, in the  $0^\circ$ – $25^\circ$  center-of-mass angular range, of the strong peak observed in the excitation energy spectrum of the daughter nucleus  ${}^{11}\text{Be}$  for the  ${}^9\text{Li} + d$  decay mode.
